WORKING PAPER · OCTOBER 2026

How long do India's district courts take? Measuring, explaining and forecasting the backlog

Arnav Goel · github.com/ArnavGoel98/CourtSight

Abstract. India's district and subordinate courts held 4.77 crore pending cases at the end of 2025, up from 2.65 crore in 2014. We combine the government's state-wise pending and disposal counts (2014–2025) with 80.8 million case records from 599 districts (filed 2010–2018). Five results follow. (i) Kaplan–Meier estimates that account for still-pending cases put the median time to a decision at 29 months for an ordinary civil suit, with 27% still undecided after five years; these estimates correct for the uneven digitisation of early records, which otherwise overstates delay. (ii) The cases filed in 2010–2018 spent 13.3 crore case-years waiting; the 2.2 crore still undecided at collection had a median age of 2.3 years. (iii) COVID added an estimated 48 lakh cases (32–70 lakh) to the backlog by the end of 2021, calibrated against the projection method's own pre-COVID errors. (iv) Across districts, caseload per courtroom does not explain slowness, and structural features explain only 10% of the variation; districts that schedule hearings further apart are markedly slower, especially for criminal cases. (v) Averages over decided cases, the usual statistic, understate delay: 17 months for civil suits against 29. An audit against the official figures finds that the case records hold about 61% of officially implied filings in 2015–2018, with large differences between states; reweighting to official filings moves the headline civil-suit median by about a month. Two negative results are reported in full: a judge-handover design fails its placebo test, and a district-level forecasting model ties, rather than beats, simple official-series forecasts for 2019. A forecast of every state's pending count on 31 December 2026 was locked by hash before the outcome exists.

1. Introduction

Delay is the most visible failure of Indian courts, and the least well measured. Official dashboards report how many cases are pending, but not how long a case takes: a pending count mixes old and new cases, and averages over decided cases alone leave out exactly the slow ones that are still waiting. This paper measures delay with methods that handle unfinished cases, puts a number on the total time spent waiting, separates the COVID shock from the trend that was already under way, and asks what slow districts have in common. It also commits to a forecast that can be checked.

The emphasis throughout is on claims that can be falsified. Each estimate is paired with a benchmark or a placebo test, the results that failed are reported alongside those that held, and every figure is rebuilt from the public repository by continuous integration.

2. Data

Official series. State-wise pending cases at 31 December for 2014–2025 and disposals for 2014–2021, transcribed from the Ministry of Law and Justice's answers to Lok Sabha questions (USQ 1838, 16 December 2022; USQ 2362, 13 February 2026), which in turn draw on the National Judicial Data Grid. The state figures are tested against the printed national totals; Kerala's 2016 disposal figure, roughly ten times its neighbouring years, fails and is excluded. Filings are never published for all years, so they are recovered from the stock–flow identity $\text{filed}_t = P_t - P_{t-1} + D_t$.

Case records. The Development Data Lab's eCourts extract (CC BY-NC-SA 4.0): 80.8 million cases filed between January 2010 and December 2018, with filing date, decision date (if any), case type, court and district. Each state was collected at a different time, between December 2018 and July 2020. A state's collection month is defined as the last month in which recorded decisions reach 20% of its 2018 monthly average; later decision dates, including typographical ones such as the year 9201, are treated as undecided. Case types are grouped into ten categories from the free-text names each court uses. The judge table gives each judge's courtroom and start and end dates.

Maps. District results are drawn on the 641 Census 2011 district boundaries (DataMeet, CC BY 4.0). DDL links 534 of its 630 court units to a 2011 district; the rest are matched by hand (renamed districts, districts carved out after 2011 shown inside their parent, and cities split into several court units), and the crosswalk is published.

What is published. Only aggregates: counts by district, filing month and decision month. No case-level rows and no names of people leave the analysis.

3. How long does a case take?

For each district and case type, the time from filing to any final disposal is estimated with the Kaplan–Meier product-limit estimator, $\hat{S}(t) = \prod_{t_i \le t}(1 - d_i/n_i)$, at monthly resolution. Cases still undecided at the collection month are right-censored there, so slow cases contribute the time they are known to have waited instead of being dropped. Intervals use Greenwood's variance. "Decided" means any disposal, including dismissal, withdrawal, settlement and transfer.

Left truncation. eCourts reached districts at different times, and cases a district had already decided when it went online were mostly never entered. Recorded filings rise from 4.3 million (2010) to 13.7 million (2018), far faster than real filings, and among cases filed in 2010 only 16% of those filed before their district's records become complete were decided within a year,

against 42% of those filed after. Pooling these survivors with complete records would overstate delay. We estimate, for each district, the month from which its records are complete (the first month after which every six-month window holds at least half its 2016–17 filing rate, and records decisions of at least a fifth of that window's filings) and let earlier cases enter the risk set only at that month (delayed-entry Kaplan–Meier), dropping those decided before it. 15% of all records are affected. 14 units whose records never meet this rule are withheld. All estimates in this paper are corrected; Section 10 reports how much this changes.

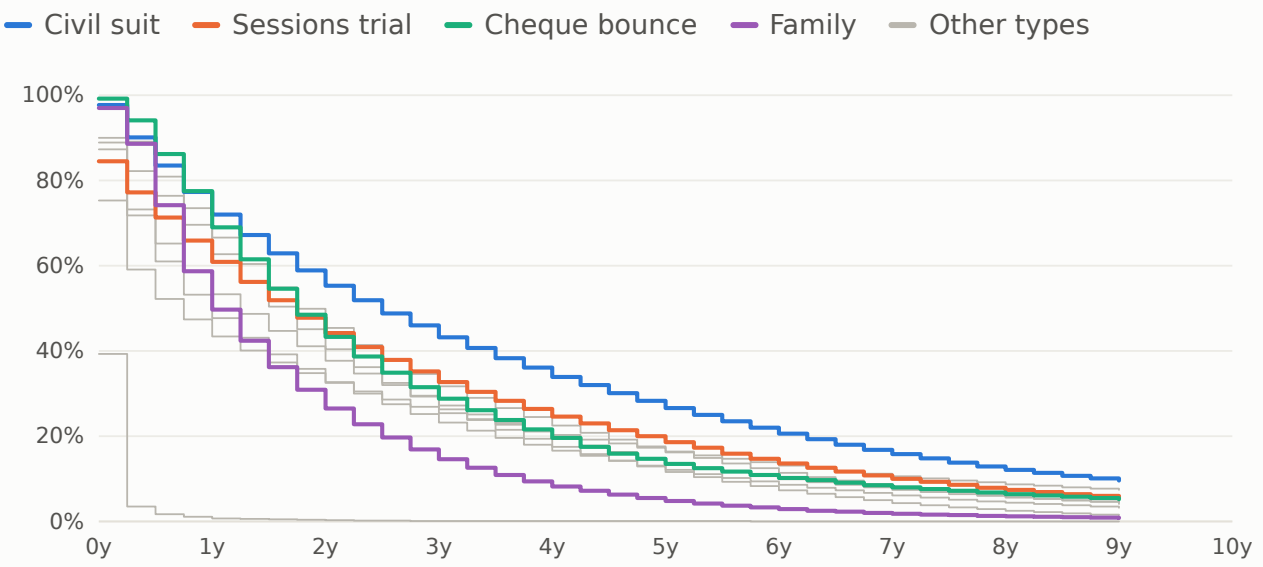

Figure 1. Share of cases still pending, by months since filing, national, by case type (Kaplan–Meier). Highlighted: civil suits, sessions trials, cheque-bounce cases and family cases.

CASE TYPE	CASES	MEDIAN (MONTHS)	PENDING AT 1 YR	AT 3 YRS	AT 5 YRS
Criminal case before a magistrate	40.3 M	8	43%	25%	16%
Civil suit (property, contract, money)	7.8 M	29	72%	43%	27%
Other / unclassified	6.9 M	15	53%	27%	14%
Sessions trial (serious crime)	5.6 M	20	61%	33%	19%
Other civil application	4.9 M	11	48%	23%	12%
Bail application	3.5 M	0	1%	0%	0%
Motor accident claim	3.0 M	19	63%	26%	12%
Execution (enforcing a decree)	2.5 M	21	67%	32%	16%
Divorce / family	1.7 M	12	50%	15%	5%
Cheque bounce (NI Act s.138)	0.8 M	21	69%	29%	14%

The ordering is stable and large. Bail applications are decided within weeks. Family cases take a median of 12 months. Civil suits are the slowest major category: median 29 months, and 27% are still pending five years after filing. Across all civil cases the median is 18 months, against 7 for criminal cases, but the criminal tail is as long: 15% of criminal cases are still pending after five years. District-level curves for 599 districts and 8 special courts are published in the interactive calculator, in English and Hindi, and on a page for each district.

Why averages over decided cases mislead. Delay is often reported as the time decided cases took. That statistic leaves out every case still waiting, and those are the slowest. Over the same records, decided civil suits took a median of 17 months against 29 with Kaplan–Meier, and decided criminal cases before a magistrate 3 months against 8. A litigant's question is closer to the second number.

4. Years of waiting

A pending count treats a case filed last month and a case filed eight years ago alike. Summing the age of each pending case at collection gives a measure of accumulated delay. Of the 80.8 million cases filed in 2010–2018, **2.2 crore** were still undecided when their state's data was collected. Together they had waited **6.4 crore case-years**; adding the time spent by the

cases decided before collection gives **13.3 crore case-years**. The median pending case had waited 2.3 years (mean 2.9); 39% had waited more than three years and 18% more than five. These are lower bounds: cases filed before 2010 are not in the data, and most cases involve two or more people.

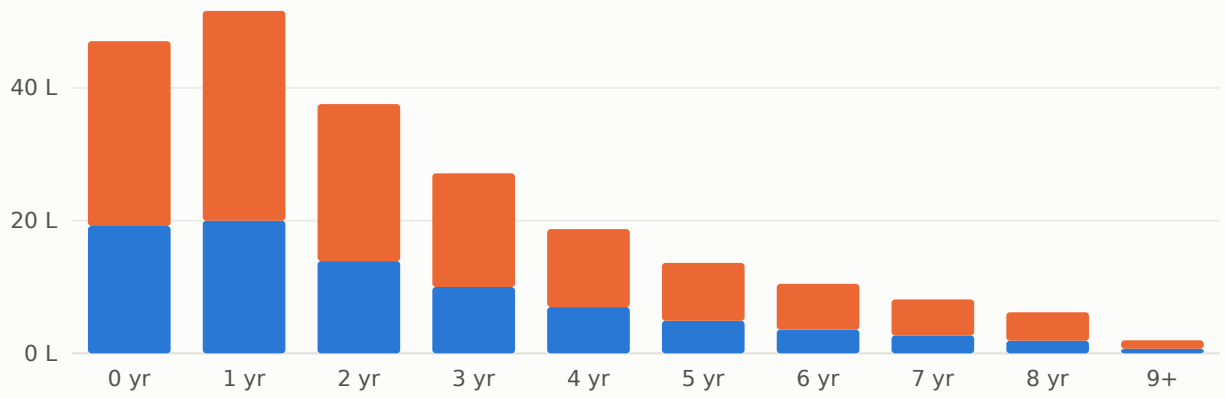

Figure 2. Cases filed 2010–2018 still pending at collection, by full years already waited. Blue: civil; orange: criminal.

5. The COVID shock

The counterfactual for each state projects its mean log growth over 2015–2019 forward from 2019, a rule fixed before post-2019 data was examined. In backtests from 2016–2018 origins, this projection under-predicted a backlog that was already accelerating (national error between about −3% and +2% per year of horizon). The headline counterfactual is corrected by the median backtest error, and its range spans the backtest errors, so the stated uncertainty is the method's own observed error rather than a model of it. By the end of 2021 the backlog stood **48 lakh** above the counterfactual (range 32–70 lakh), 12% of the stock. The gap narrows after 2022, and by 2025 the range includes zero.

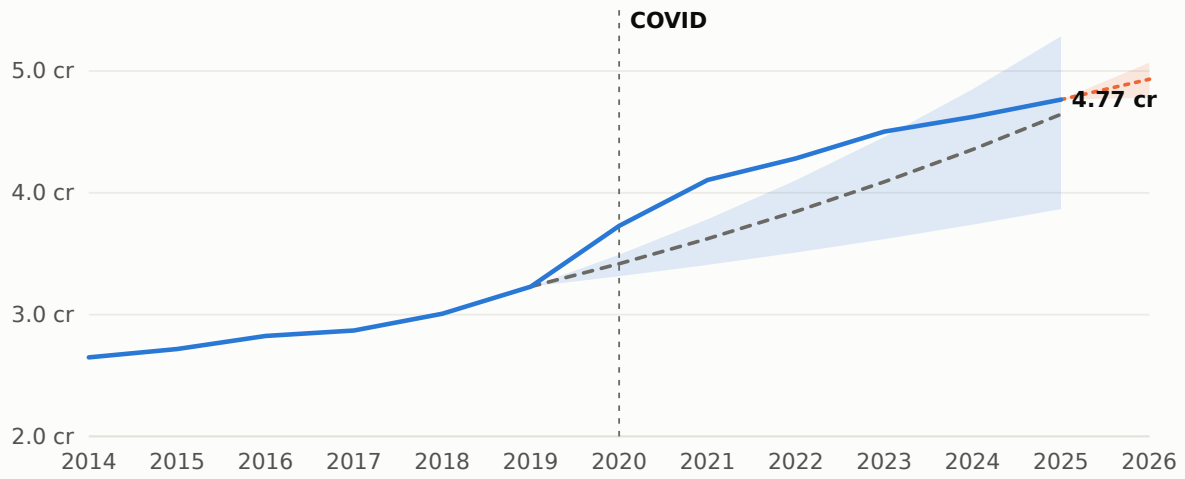

Figure 3. Pending cases at year end (blue), the no-COVID counterfactual with its backtest-calibrated range (grey), and the locked 2026 forecast with its 10–90% range (orange).

At the 2023–2025 pace, the national backlog grows by about 13 lakh cases a year and does not clear; clearing it within ten years would take about 61 lakh extra decisions every year, 36% more than courts decided in 2021.

6. What do slow districts have in common?

For 571 districts with at least 2,000 cases, the outcome is the share of civil cases still pending three years after filing (Kaplan–Meier). It ranges from 17% in the fastest tenth of districts to 48% in the slowest. We regress it on standardised district features computed from the case and judge records for 2014–2017: caseload per active courtroom (log), district size (log annual filings), the criminal share of filings, the median months a judge stays in one courtroom, and, as a control for data coverage, the year the district's records become complete. The 95% intervals come from 2,000 bootstrap resamples of districts.

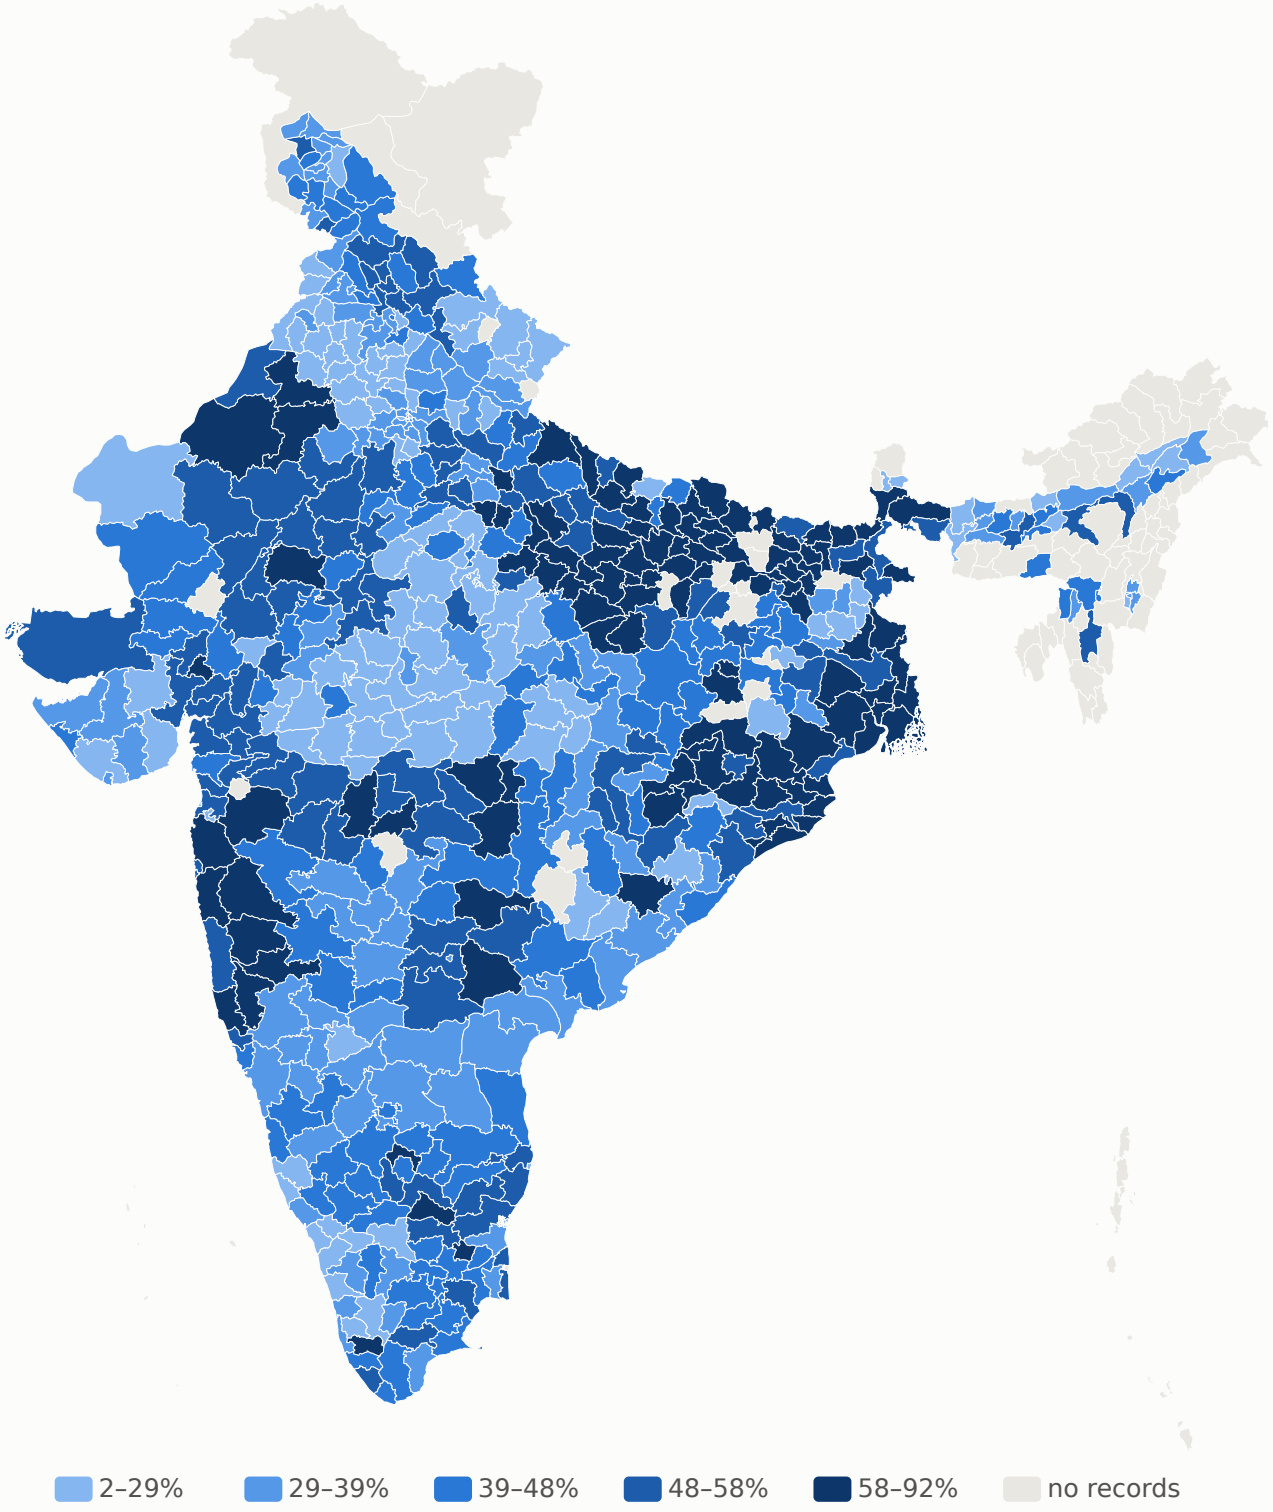

Figure 4. Share of civil suits still pending three years after filing, by district (2011 Census boundaries; districts created later are pooled with their parent). Shades are fifths of districts. Grey: no court records in the data. Interactive version with every case type: arnavgoel98.github.io/CourtSight/map.html.

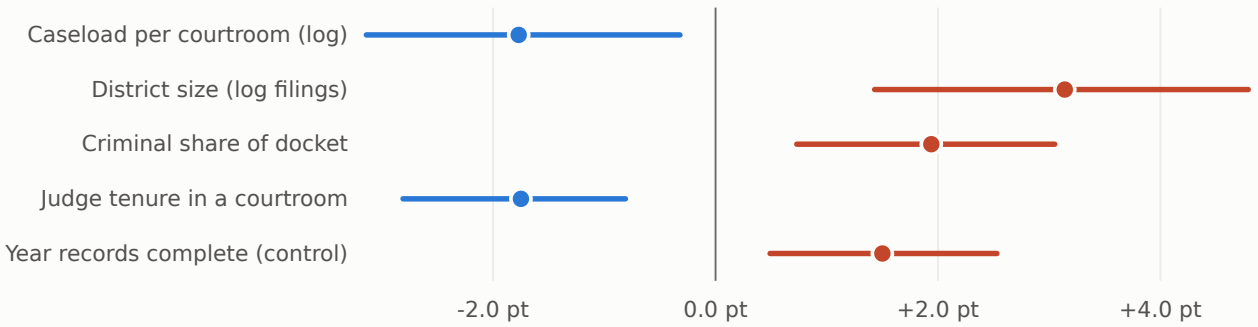

Figure 5. Change in the share of civil cases pending after three years for a one-standard-deviation increase in each feature, with 95% bootstrap intervals.

Caseload per courtroom, the usual explanation, goes with slightly faster courts once district size is held fixed, not slower ones (−1.8 percentage points per standard deviation, interval −3.1 to −0.3). Longer judge tenure goes with faster courts (−1.8 points per SD of about 7 months), and a heavier criminal docket with slower civil cases (+1.9 points). Together these features explain only **10%** of the variance between districts. A throughput variable (decisions ÷ filings) raises this to 45%, but it is close to a restatement of the outcome and is not interpreted. These are cross-sectional correlations: districts with longer-serving judges may differ in many other ways, and most of what makes a district slow (local practice, adjournments, vacancies, the bar) is not recorded in this data.

7. Where cases get stuck, and how far apart hearings are

For each case pending at collection, the records give the purpose of its next listing (free text typed by court staff) and the dates of its last and next listings. Of the 2.13 crore such cases, **37%** were next listed for summons, notices or appearance, that is, for getting the parties before the court; 22% for evidence; 7% for framing charges or issues; 16% for applications and general hearings; and 10% for arguments, orders or judgment. The next hearing was set a typical (geometric mean) 56 days after the last: 69 days at the summons stage, 49 at evidence. Across districts, leaving out the three states whose hearing records look stale (Mizoram, Odisha, West Bengal), the typical gap runs from 34 days in the tenth of districts with the shortest gaps to 72 in the tenth with the longest.

Longer gaps go with slower courts (Figure 6). In the fifth of districts with the shortest gaps, 14% of criminal cases were still pending three years after filing; in the fifth with the longest, 31% (civil: 28% and 34%). Unlike caseload per courtroom, the gap keeps its association when caseload, district size, case mix, judge tenure and record completeness are held fixed: gaps one standard deviation longer go with 6.8 percentage points more criminal cases pending at three years (interval 5.7 to 7.9) and 2.7 points more civil cases, and with the gap included the model accounts for 32% of the variation between districts in criminal delay (20% civil). It also survives giving every district the national stage mix, and comparing districts only within their own state (Spearman ρ = 0.42 criminal, 0.33 civil). The direction of

cause is open: congested courts may space hearings out because they are congested. But the result points to the scheduling of hearings, rather than the number of cases per courtroom, as the place where slow and fast districts differ.

The labels limit what can be said. Police "final form" and charge-sheet labels, which come before a trial, make up 1.7% of pending cases and fall in "arguments, orders or judgment"; 1.4% have no label; and "appearance" can be a routine date on which nothing else happens. The gaps are the ones scheduled, not the time a case actually waited, and they describe only cases still pending at collection.

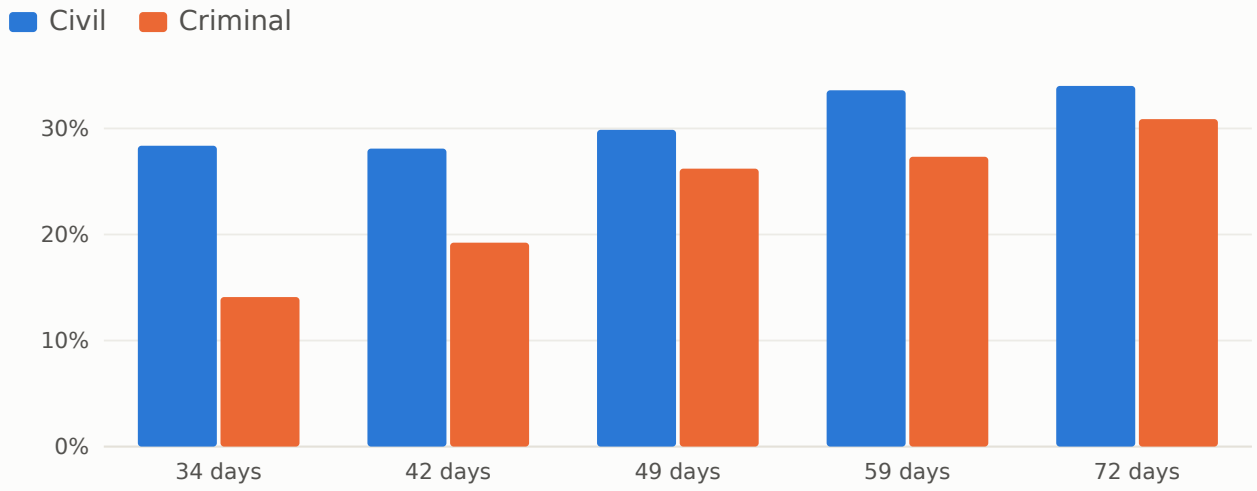

Figure 6. Share of cases still pending three years after filing (median district), by fifths of districts from the shortest to the longest typical gap between hearings. West Bengal, Odisha and Mizoram, whose hearing records look stale, are left out.

8. Does a change of judge slow a courtroom? A failed design

Judges in India are transferred often, and a new judge must learn a docket. We built a stacked difference-in-differences event study around 11,142 judge handovers in 447 districts: each courtroom's monthly disposals relative to its own previous twelve months, minus the same for same-district courtrooms without a change, with a district block bootstrap. A planted synthetic −30% effect is recovered. On real data, disposals are about 10% lower in the year after a handover.

The design does not pass a placebo test. Moving every handover 18 or 30 months earlier, to dates when no judge changed, still yields drops of 8% and 7%. The decline is under way before the new judge arrives; the comparison picks up courtrooms that were already slowing. We therefore report no estimate. A further limitation: courtroom numbers in the judge and case tables agree in only 42% of judge-months.

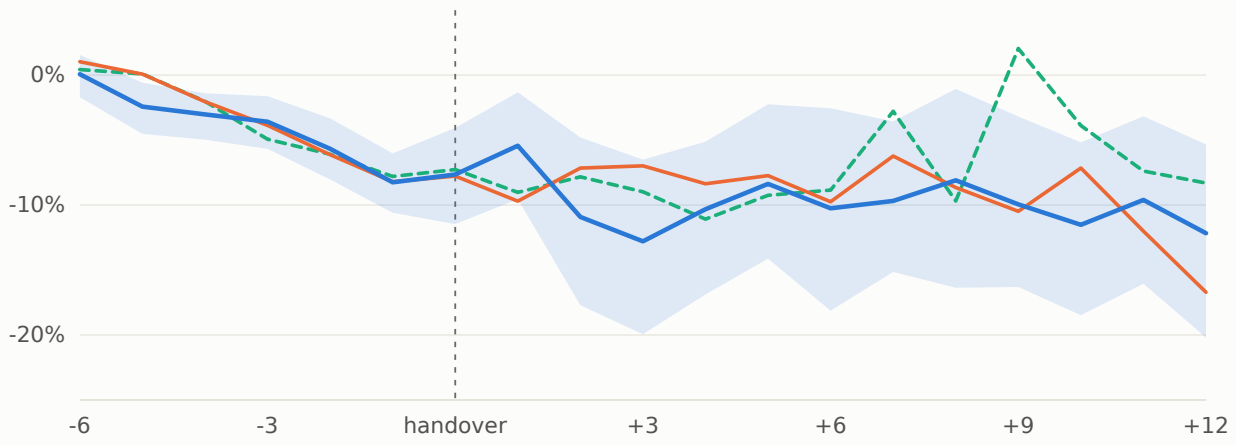

Figure 7. Disposals relative to pre-handover levels, by month from the handover: real dates with 95% interval (blue), and placebo dates 18 (orange) and 30 (green) months earlier.

9. Forecasting, and grading forecasts honestly

2019, graded. A district-level LightGBM quantile model trained on the case records beats the best simple forecast by 12–25% (pinball loss) on held-out 2016 and 2017 origins. Its 2019 state forecasts were committed before any 2019 outcome was examined and then scored against the official figures for 27 states. At state level it matches simple forecasts built from the official series (mean absolute error of backlog growth 0.077, against 0.075 for a common rate and 0.076 for repeating 2018) but does not beat them. We report this as a tie.

2026, locked. Pending cases on 31 December 2026, for every state, were forecast from data through 2025 with a method chosen by a rule fixed before any backtest (lowest case-weighted error of one-year state log growth across six target years). The national median forecast is **4.93 crore** (10–90%: 4.78–5.07 crore). The forecast files were committed on 8 October 2026 (commit `84732fc`) and are guarded by a test that fails if they change. SHA-256 of the state forecast file:

`adf62cd20085e545730b10e62a7ffa66dae5e3f90207d197c5207f2aa5c96d2d`

The forecast will be graded once the government publishes the 2026 figure.

10. Auditing our own results

We looked for ways the data could mislead and report each check, including the ones that changed our numbers.

- **Digitisation (left truncation).** Described in Section 3. Before the correction, ordinary civil suits had a median of 32 months; after it, 29. Nationally the change is modest, but 1,031 of 4,596 district × case-type results moved by more than 5 percentage points,

and the civil-suit ranking of districts shifted by a median of 23 places (up to 278). Varying the completeness threshold from 30% to 70% puts the civil-suit median at 28–30 months.

- **Collection date.** Moving the rule that dates each state's collection from 20% of normal monthly decisions to 10% or 40% puts the civil-suit median at 29–32 months.
- **Precision of rankings.** Simulating each district's 3-year figure from its sampling interval gives a 90% range for its rank. For civil suits the median range spans 19 places, and 15% of districts have ranges wider than 50 places; the published rankings show these ranges.
- **Units that are not districts.** 8 units in the source data are special courts or court complexes (for example Mumbai City Civil Court); they are labelled as such.
- **Districts that never recorded decisions.** Filings alone can look complete while decisions are missing. In 14 court units, including Gaya, Muzaffarpur, Bhojpur and Vaishali in Bihar and Chandauli in Uttar Pradesh, the records hold almost no decisions before 2018 (Gaya: 33 decisions in 2010–2017 against 7,969 in 2018), so every case looks stuck. An earlier version of this analysis ranked these units the slowest in India. The completeness rule now also requires recorded decisions of at least 20% of filings in every six-month window. Units that never pass are withheld, and 10% or 35% thresholds give a civil-suit median of 29–30 months.
- **The age of the pending stock against NJDG.** The National Judicial Data Grid's age bands for pending district-court cases on 24 May 2020 (as reported in the press) can be compared with these records for the ages they fully cover. Among cases aged 1–10 years in the 28 states collected by December 2019, the records give 52%, 26% and 22% aged 1–3, 3–5 and 5–10 years; NJDG gives 48%, 26% and 26%. The records start in 2010, so their oldest band runs slightly low.
- **Coverage of the court system.** The official figures imply each state's filings through the stock–flow identity (pending at year end minus pending a year earlier, plus disposals). Against them, the eCourts records hold 61% of 2015–2018 filings, rising from 55% in 2015 to 67% in 2018. Coverage ranges from 8% in Tripura to roughly all cases in Bihar, and 5 states and union territories have no records. The identity also counts transfers and restorations, so single state-years are only indicative. The results therefore describe the courts that eCourts recorded. Two checks suggest the headline figures are not driven by the gaps: weighting each state by its official filings gives a civil-suit median of 30 months (published: 29), and counting every record only from January 2014 gives 29. Across 22 states, coverage and the civil-suit share pending at 3 years are only weakly related (Spearman $\rho = -0.09$). Whether the missing cases differ from the recorded ones cannot be checked with this data.
- **Are pending records live?** A decision that was never entered would leave a case looking pending and a court looking slow. Among cases pending at collection, 4.9% had last been listed for a hearing more than 12 months before their state's collection month, and 0.4% more than 24 months. In Bihar, home of many of the slowest districts, the share is 1.2%. The exceptions are West Bengal (53%) and Odisha (29%), whose delays may be overstated.

- **An apparent speed-up.** Within complete records, the share of cases decided within a year rises from 42% for 2010 filings to 56% for 2017 filings. Holding the case-type mix fixed, it rises from 44% to 54%. Splitting states by whether their coverage was steady in 2015–2018, the steady states rose from 47% to 59%, and states whose records were still filling in rose from 53% to 56%. The rise is no larger where records were still filling in, so coverage does not explain it. About 4 points of it is case mix; the rest may be a real speed-up, which this data cannot confirm. Our pooled figures describe 2010–2018 filings, not courts today.
- **Slow-district correlates.** Districts whose records start late have shorter observed judge postings, which could have produced the tenure association artificially. With the corrected outcome and the records-complete year as a control, it holds.

11. Limitations

- No public case-level data exists after 2018. The official 2023–2025 series has no disposal figures, and some state series jump in single years (Tripura −75%, Uttarakhand −17%).
- "Decided" includes dismissals, withdrawals and transfers; a transfer can end one case record and open another.
- Case-type grouping relies on court-specific names; 9% of cases fall in "other".
- Nothing here identifies how many judges would be needed, or what would happen if a policy changed. The district analysis is descriptive, and the one causal design attempted failed.
- High Courts and the Supreme Court are not covered.
- Cases filed before 2010 are absent, so ages of pending cases and case-years of waiting are lower bounds; decided cases from before each district's records became complete are under-counted in the total case-years.

12. Conclusion

Measured properly, delay in India's district courts is longer than averages over decided cases suggest, and the backlog was growing before COVID and is still growing after it. The variation between districts is large and is mostly not explained by caseload per courtroom; it tracks how far apart hearings are scheduled much more closely. That argues for studying how courts work, not just how many there are. The methods, data aggregates, interactive tools and a forecast waiting to be graded are public, so each claim here can be checked and, if wrong, corrected.
